# Trigonometry: Law of Sines, Law of Cosines, and Area of Triangles 

Formulas, notes, examples, and practice test (with solutions)

Topics include finding angles and sides, the "ambiguous case" of law of Sines, vectors, navigation, and more.

## Law of Sines

What is it? Equations that relate the interior angles of a triangle to their corresponding (opposite) sides.
In a triangle, "the ratio of a side to the sine of its opposite angle is the same for all 3 angle/sides"

## Law of Sines

$$
\frac{\sin A}{a}=\frac{\sin B}{b}=\frac{\sin C}{c}
$$

Examples:

1) Given the following triangle, find the measure of angle $x$.

2) Given the following triangle, find the length of s .

3) Verify the law of sines for a 30-60-90 triangle.
(Right triangle)
(Obtuse triangle)
First, we must identify the measure of the angle opposite $8 \ldots$
$180=137+20+$ ?
The angle opposite is 23 degrees...
then, we can use law of sines:

$$
\begin{aligned}
& \frac{\sin 23^{\circ}}{8}=\frac{\sin 137^{\circ}}{\mathrm{S}} \\
& \mathrm{~s}=\frac{8(\sin 137)}{\sin 23}=13.96
\end{aligned}
$$

$$
\begin{aligned}
& \frac{\operatorname{Sin} 40}{6}=\frac{\operatorname{Sin} x}{9} \\
& \sin x=\frac{9(\sin 40)}{6}=.964 \\
& x=\arcsin (.964)=73.74^{\circ}
\end{aligned}
$$

$$
\begin{gathered}
\frac{\sin 90^{\circ}}{2 \mathrm{x}}=\frac{\sin 30^{\circ}}{\mathrm{x}}=\frac{\sin 60^{\circ}}{\sqrt{3} \mathrm{x}} \\
\frac{1}{2 \mathrm{x}}=\frac{1 / 2}{\mathrm{x}}=\frac{\sqrt{3} / 2}{\sqrt{3} \mathrm{x}}
\end{gathered}
$$

x

What is it? Equations that relate the interior angles of a triangle to their corresponding (opposite) sides.
In a triangle, "two known sides and the included angle can determine the length of the 3 rd side"

Law of Cosines

$$
\begin{aligned}
& \mathrm{a}^{2}=\mathrm{b}^{2}+\mathrm{c}^{2}-2 \mathrm{bc}(\cos \mathrm{~A}) \\
& \mathrm{b}^{2}=\mathrm{a}^{2}+\mathrm{c}^{2}-2 \mathrm{ac}(\cos \mathrm{~B}) \\
& \mathrm{c}^{2}=\mathrm{a}^{2}+\mathrm{b}^{2}-2 \mathrm{ab}(\cos \mathrm{C})
\end{aligned}
$$

Note the pattern of the formulas:

Examples:

1) Given the following triangle, find the length of d .

Since we know 2 sides and the included angle, we can use law of cosines:

$$
\begin{aligned}
& d^{2}=14^{2}+16^{2}-2(14)(16)(\cos 37) \\
& d^{2}=196+256+448(.7986) \\
& d^{2}=94.2 \quad d=9.7
\end{aligned}
$$

2) Given the following triangle, find the measure of angle x .

$$
\begin{gathered}
10^{2}=8^{2}+16^{2}-2(8)(16)(\cos x) \\
100=64+256-256(\cos x) \\
-220=-256(\cos x) \\
\cos x=.859 \\
x=30.75^{\circ}
\end{gathered}
$$

Let's check the answer by finding the other 2 angles:

$$
\text { Law of Cosines: } \begin{array}{rlrl}
8^{2} & =10^{2}+16^{2}-2(10)(16)(\operatorname{cosy}) \\
64 & =100+256-320(\operatorname{cosy}) \\
-292 & =-320(\operatorname{cosy}) \\
y & =24.15^{\circ} \\
16^{2} & =8^{2}+10^{2}-2(8)(10)(\operatorname{cosz}) \\
256 & =64+100 & \\
92 & =-160(\operatorname{cosz}) \\
\mathrm{x}+\mathrm{y}+\mathrm{z}= \\
\mathrm{z} & =125.1^{\circ} & \begin{array}{l}
\text { (and, smallest angle is opposite }
\end{array} \\
\text { (he smallest side; largest side is }
\end{array}
$$

Example: Find the 3 angle measurements in triangle $A B C$
Step 1: Find 1st angle using law of cosines

$$
\begin{aligned}
\mathrm{a}^{2} & =\mathrm{b}^{2}+\mathrm{c}^{2}-2 \mathrm{bc}(\cos \mathrm{~A}) \\
21^{2} & =20^{2}+25^{2}-2(20)(25)(\cos \mathrm{A}) \\
441 & =400+625-1000(\cos \mathrm{~A}) \\
-584 & =-1000(\cos \mathrm{~A}) \\
\mathrm{A} & =54.27^{\circ}
\end{aligned}
$$

Step 2: Find 2nd angle using law of sines

$$
\begin{gathered}
\frac{\sin A}{a}=\frac{\sin B}{b} \\
\frac{\sin (54.27)}{21}=\frac{\sin B}{20} \\
\sin B=\frac{20(\sin 54.27)}{21}=.773 \\
B=50.64^{\circ}
\end{gathered}
$$

Step 3: Find 3rd angle using geometry theorem: (sum of interior angles of $\triangle$ is 180 degrees)

$$
\begin{gathered}
\angle \mathrm{A}+\angle \mathrm{B}+\angle \mathrm{C}=180^{\circ} \\
54.27^{\circ}+50.64^{\circ}+\angle \mathrm{C}=180^{\circ} \\
\angle \mathrm{C}=75.09^{\circ}
\end{gathered}
$$

To check the answer:
a) observe the side lengths/angles

$$
\begin{aligned}
\mathrm{c}>\mathrm{a}>\mathrm{b} & \text { and } & \mathrm{C}>\mathrm{A}>\mathrm{B} \\
25>21>20 & \text { and } & 75.09>54.27>50.64
\end{aligned}
$$

note: angles $A$ and $B$ have close measures, and sides a and b have close measures..
b) use law of sines

$$
\begin{aligned}
& \frac{\sin A}{a}=\frac{\sin B}{b}=\frac{\sin C}{c} \\
& \frac{\sin (54.27)}{21}=\frac{\sin (50.64)}{20}=\frac{\sin (75.09)}{25}=.03865 \quad \text { All have the same ratio }
\end{aligned}
$$

c) use law of cosines to check b or c

$$
\begin{aligned}
& \mathrm{c}^{2}=\mathrm{a}^{2}+\mathrm{b}^{2}-2 \mathrm{ab}(\cos \mathrm{C}) \\
& 25^{2}=21^{2}+20^{2}-2(21)(20)(\cos 75.09) \\
& 625=441+400-216.13 \\
& 625
\end{aligned}
$$

## Vectors \& Law of Sines/Cosines: Applications

Example: An airplane flies due East at an air speed of 500 miles per hour.
A crosswind flows (from the Northwest) toward the Southeast at a rate of 50 miles per hour.
What is the ground speed and direction of the airplane?

Airplane can be expressed as a vector:

Crosswind can be expressed as a vector:

The groundspeed is the sum of the vectors...

We can transform the vectors into a triangle:

Use Law of Cosines to find ground speed of airplane:

$$
\begin{aligned}
\mathrm{c}^{2} & =\mathrm{a}^{2}+\mathrm{b}^{2}-2 \mathrm{ab}(\cos \mathrm{C}) \\
& =(500)^{2}+(50)^{2}-2(500)(50)(\cos 135) \\
& =250000+2500-50000(.707) \\
& =287,855 \\
& \mathrm{c} \cong 536.5 \text { miles }
\end{aligned}
$$

$$
\begin{aligned}
& \text { Using Vectors: } \quad V_{a}=500 \mathrm{i}+0 \mathrm{j} \\
& \mathrm{~V}_{\mathrm{c}}=\frac{50}{\sqrt{2}} \mathrm{i}-\frac{50}{\sqrt{2}} \mathrm{j}=25 \sqrt{2} \mathrm{i}-25 \sqrt{2} \mathrm{j} \\
& \mathrm{~V}_{\mathrm{a}}+\mathrm{V}_{\mathrm{c}}=535.35 \mathrm{i}-35.35 \mathrm{j} \\
& \text { groundspeed }=\left\|\mathrm{V}_{\mathrm{a}}+\mathrm{V}_{\mathrm{c}}\right\|=\sqrt{535.35^{2}+(-35.35)^{2}} \\
& =536.5 \\
& \text { direction }=\arctan [(-35.35) / 535.35]=-3.8^{\circ}
\end{aligned}
$$

Then, use the Law of Sines to find the direction:

$$
\begin{aligned}
\frac{\sin A}{a} & =\frac{\sin B}{b} \\
\frac{\sin (135)}{536.5} & =\frac{\sin (B)}{50} \\
\sin (B) & =\frac{50 \sin (135)}{536.5} \\
B & =3.8^{\circ}
\end{aligned}
$$

The plane is going N93.8E
or

| S86.2E |
| :--- | :--- |
| or |

3.8 degrees south of due east

Example: To find the distance across a lake, a surveyor took the following measurements: What is the distance across the lake?

Looking at the 'triangle', we have Side-Angle-Side...
So, we can use law of cosines to find the other side!

$$
\begin{aligned}
\mathrm{d}^{2}= & (7)^{2}+(8.5)^{2}-2(7)(8.5)\left(\cos 37^{\circ}\right) \\
& =121.25-119(.799)=26.21
\end{aligned}
$$

the distance (d) across the lake is approximately

Note: the answer is 'reasonable', because 37 degrees is likely the smallest angle; therefore, the opposite side should be less than 7 and $8.5 \ldots$ To check, use law of sines to find the other angles...

Example: A sailor at sea looks at coordinates on the following map: How far is Gilligan's island from his home?

At first, we have a triangle with 2 sides...

Using geometry properties/theorems, we can find a helpful angle!

1) "If parallel lines are cut by a transversal,
 then alternate interior angles are congruent"

$$
65 \text {----> } 65
$$

2) "The sum of adjacent angles on a straight line is 180 degrees"

$$
10+65--->\text { other angle is } 105
$$

3) If you know 2 sides of a triangle and the included angle, then you can use law of cosines to determine the 3rd side

$$
\begin{aligned}
& d^{2}=(40)^{2}+(22)^{2}-2(40)(22)(\cos 105) \\
& d^{2}=1600+484-1760(-.259)=2539.5 \\
& \text { therefore, } d=50.4 \text { miles }
\end{aligned}
$$

Example: A plane is approaching an airport runway that is 9000 feet long.
The angle of declination to each end of the runway is 17.7 and 19.1 degrees.
a) What is the air distance to the airport runway?
b) What is the altitude of the plane?
c) What is the ground distance to the runway?

Alternate interior angles: 19.1
Supplementary angles: $19.1+160.9=180$

Air distance:

$$
\begin{aligned}
& \text { Use Law of Sines } \\
& \frac{\mathrm{AD}}{\operatorname{Sin}(17.7)}=\frac{9000}{\operatorname{Sin}(1.4)} \\
& \mathrm{AD}=\frac{9000 \operatorname{Sin}(17.7)}{\operatorname{Sin}(1.4)} \cong 111,996 .
\end{aligned}
$$

Altitude:
Use trig function Sine:

$$
\begin{gathered}
\operatorname{Sin}(19.1)=\frac{\mathrm{h}}{111,996} \\
\mathrm{~h} \stackrel{N^{\prime}}{=} 36,647
\end{gathered}
$$

Ground distance:

Use trig function Cosine:

$$
\operatorname{Cos}(19.1)=\frac{\mathrm{g}}{111,996}
$$

(also, pythagorean theorem:

$$
\left.\mathrm{h}^{2}+\mathrm{g}^{2}=111,996\right)
$$

$\mathrm{g} \xlongequal{\cong} 105,830$

The "ambiguous case": Law of Sines (SSA)

When given two sides and a non-included angle, there may be 3 possible outcomes.

## Outcome 1: Zero Solutions

Example: Given triangle STU; $\mathrm{s}=5$

$$
t=7
$$

$$
\angle \mathrm{S}=126^{\circ}
$$

Since 5 is opposite the obtuse angle (and is NOT the largest side), this triangle cannot exist...

$$
\sin (T)=\frac{7 \sin (126)}{5}=1.13
$$

$$
\sin \ngtr 1
$$

## Outcome 2: One Solution

Example: Given triangle $\mathrm{PQR} ; \mathrm{p}=8$

$$
\begin{aligned}
& \mathrm{q}=13 \\
& \mathrm{Q}=116^{\circ}
\end{aligned}
$$

$$
\frac{\sin (126)}{5}=\frac{\sin (T)}{7}
$$

Example: Given triangle $\mathrm{ABC} ; \mathrm{a}=12$

$$
\mathrm{b}=18
$$

$$
\angle \mathrm{A}=28^{\circ}
$$

$\frac{\sin (28)}{12}=\frac{\sin (B)}{18}$

$$
\begin{aligned}
\sin (B)= & \frac{18 \sin (28)}{12}=.704 \\
& B=44.8 \quad \text { (approximately) }
\end{aligned}
$$

Since $A=28$ and $B=44.8$, angle $C$ is 107.2 degrees

Remember, $\sin ^{-1}(.704)$ has another answer in quadrant II (where sine is also positive!)

$$
\sin ^{-1}(.704)=135.2^{\circ} \quad \sin (135.2)=.704
$$

Assuming the missing angle $B$ is 135.2 ,
and angle $A$ is 28 ,
angle C is 16.8 degrees!

The area of a triangle is $\frac{1}{2}$ (base)(height)
When the height (altitude) is given, simply substitute the values:

If it's a right triangle, use one of the legs as the base:

What if it's not a right triangle and the height is not given?

$$
\text { Area of triangle }=\frac{1}{2} \mathrm{ab}(\operatorname{Sin} \mathrm{C})
$$

where a and b are sides and C is the included angle

lower case letter is the side opposite the upper case angle

Example: Find the area:

Since just 1 angle is given, the easiest choice is the 2 adjacent sides with that angle:

Area $=\frac{1}{2}(9)(11) \sin \left(73^{\circ}\right)=\frac{99}{2}(.956)=47.34$

Example: What is the area of a triangle with sides 9,13 , and 20 ?

Step 1: Sketch the triangle

## Step 2: Find an angle

Use law of cosines: $c^{2}=a^{2}+b^{2}-2 a b(\cos C)$

$$
\begin{aligned}
& a=13 \\
& b=20 \\
& c=9
\end{aligned}
$$

**suggestion: find an acute angle rather than an obtuse angle

$$
\begin{aligned}
81 & =169+400-520(\cos \mathrm{C}) \\
-488 & =-520 \cos \mathrm{C} \\
.938 & =\cos \mathrm{C}
\end{aligned}
$$

Heron's (or Hero's) Formula

$$
\text { area of triangle }=\sqrt{s(s-a)(s-b)(s-c)}
$$

where $\mathrm{a}, \mathrm{b}, \mathrm{c}$ are sides of the triangle

$$
\text { and } \mathrm{s}=\frac{\mathrm{a}+\mathrm{b}+\mathrm{c}}{2}
$$

Example: What is the area of the triangle?

We are given 3 sides (but, no angles), so we'll use Heron's Formula
$s=\frac{5+6+7}{2}=9$
Then, the area $=\sqrt{9(9-5)(9-6)(9-7)}$
$=\sqrt{9 \cdot 4 \cdot 3 \cdot 2}=14.7$

Example: Use 3 methods to find area of this right triangle

1) $\quad$ Area $=1 / 2$ (base)(height)

$$
=1 / 2(3)(4)=6
$$

2) Heron's Formula: $\quad$ Area $=\sqrt{\mathrm{s}(\mathrm{s}-\mathrm{a})(\mathrm{s}-\mathrm{b})(\mathrm{s}-\mathrm{c})}$

$$
\text { semiperimeter } s=\frac{12}{2}=6
$$

Area $=\sqrt{6(6-5)(6-4)(6-3)}=\sqrt{36}=6$
3) Using Sine: Area $=\frac{1}{2} \mathrm{ab}(\sin \mathrm{C})$

Since we are given a right angle, we'll use that angle and the adjacent sides:

$$
\text { Area }=\frac{1}{2}(3)(4) \sin \left(90^{\circ}\right)=6
$$

PRACTICE QUIZ --

Law of Sines and Cosines Quiz

1) Find $x$ :

2) Find $\ominus$ :

3) $\mathrm{a}=6$
$\mathrm{b}=8$
$\angle \mathrm{c}=53^{\circ}$
Find the other angle measures and side lengths of the triangle:
```
Law of Sines and Cosines Quiz
```

4) Find the other parts of the triangle:

5) Find the missing sides and angles:

6) Given: $\angle \mathrm{A}=28^{\circ}$
$\mathrm{a}=7$
b $=17$

Find: $\angle \mathrm{B}=$
$\angle \mathrm{C}=$
$\mathrm{c}=$
7) Given: $\angle \mathrm{A}=40$
$\mathrm{a}=8$
$\mathrm{b}=11$
Find: $\angle \mathrm{B}=$
$\angle \mathrm{C}=$
c $=$
8) To find the distance across a lake, a surveyor took the following measurements: What is the distance across the lake?

9) A sailor at sea looks at coordinates on the following map: How far is the paradise island from his home?

10) Triangle GUM has sides measuring 7,8 , and 13 ..

What are the angle measures?
What is the area of the GUM?
11) Find the area of the interior of the triangle.
a) Use the trig area formula $\frac{1}{2} \mathrm{ab}(\sin (\mathrm{C}))$
b) Then, use Heron's formula to check your answer.

12) How tall is the tower?

SOLUTIONS $-\rightarrow$

## Law of Sines and Cosines Quiz

## 1) Find $x$ :

Since we're given 2 sides and the included angle, we can use law of cosines..
$c^{2}=a^{2}+b^{2}-2 a b(\cos c)$

## SOLUTIONS

$$
x^{2}=(38)^{2}+(41)^{2}-2(38)(41)\left(\cos 39^{\circ}\right)
$$

$$
x^{2}=1444+1681-3116(.777)
$$

$$
x^{2}=3125-2421.59=703.41
$$

$$
\begin{aligned}
& \mathrm{x}=26.52 \begin{array}{l}
\text { (note: since } \mathrm{x} \text { is oppd } \\
\text { the smallest angle, it }
\end{array}
\end{aligned}
$$ the smallest angle, it

must be the smallest side!)

## 2) Find $\ominus$ :

Since we know 3 sides, we can use law of cosines to find the (included) angle..

$$
c^{2}=a^{2}+b^{2}-2 a b(\cos c)
$$

3) $\mathrm{a}=6$
$\mathrm{b}=8$
$\angle \mathrm{c}=53^{\circ}$
Find the other angle measures and side lengths of the triangle:

First, draw a sketch of the triangle:
To find side " c " (opposite $\angle \mathrm{c}$ ), use law of cosines:
$c^{2}=(6)^{2}+(8)^{2}-2(6)(8)\left(\cos 53^{\circ}\right)$
$c^{2}=100-96(.602)$
$\mathrm{c}^{2}=42.2 \quad \mathrm{c}=6.5$ (obviously, length is NOT -6.5 )
To find another side, use law of sines:

$$
\begin{array}{rlr}
\frac{\sin A}{a}=\frac{\sin B}{b}=\frac{\sin C}{c} \\
& \frac{\sin B}{8}=\frac{\sin (53)}{6.5} & \frac{\sin A}{6}=\frac{\sin (53)}{6.5}
\end{array}
$$

Check: $53+79.4+47.5=179.9 \cong 180^{\circ}$
smallest side a is opposite smallest angle A middle side $c$ is opposite middle angle $C$ largest side b is opposite largest angle B

## V

$\sin B=\frac{8 \sin (53)}{6.5}=.983$

$$
\mathrm{B}=79.4^{\circ}
$$

$$
\begin{aligned}
& \sin \mathrm{A}=\frac{6 \sin (53)}{6.5}=.737 \\
& \mathrm{~A}=47.5^{\circ}
\end{aligned}
$$

Law of Sines and Cosines Quiz
4) Find the other parts of the triangle:

SOLUTIONS
sum of interior angles of triangle $=180^{\circ}$
$23+52+\mathrm{A}=180$
so, $\angle \mathrm{A}=105^{\circ}$
Then, use law of sines
$\begin{array}{lc}\frac{\sin \mathrm{A}}{\mathrm{a}}=\frac{\sin 23}{8} & 8 \sin (105)=\mathrm{asin}(23) \\ \frac{\mathrm{sin} 23}{8}=\frac{\sin 52}{\mathrm{c}} & 8 \sin (52)=\frac{8(.966)}{(.391)} \\ & 19.78 \\ & \mathrm{c}=\frac{8(.788)}{(.391)} \\ & 16.13\end{array}$
5) Find the missing sides and angles:

Suppose we want to use law of sines:

$$
\frac{\sin 35}{14}=\frac{\sin 55}{\mathrm{~b}} \quad \mathrm{~b}=\frac{14 \sin 55}{\sin 35}=19.99
$$

Since the given angles, 55 and 35 , add up to 90 , angle $C$ is a right angle! so, we can use basic trig functions:

$$
\begin{array}{ll}
\tan 55=\frac{b}{14} & \mathrm{~b}=14(\tan 55)=14(1.428)=19.99 \\
\sin 35=\frac{14}{\mathrm{c}} & \mathrm{c}=\frac{14}{\sin 35}=\frac{14}{.574}=24.41
\end{array}
$$

note: to check, use pythagorean theorem:

$$
(14)^{2}+(19.99)^{2}=(24.41)^{2}
$$

6) Given: $\angle \mathrm{A}=28^{\circ}$
$\mathrm{a}=7$
b $=17$
Find: $\angle \mathrm{B}=$ $\angle \mathrm{C}=$
c $=$

Since this is a SSA case, we may have 0,1 , or 2 solutions...

$$
\frac{\sin 28}{7}=\frac{\sin B}{17} \quad \sin B=\frac{17(.469)}{7}=1.14
$$

Here is a sketch:
since $\sin B>1$, there is no solution!
observe the similarities

7) Given: $\angle \mathrm{A}=40 \quad$ SOLUTIONS

$$
\begin{aligned}
& \mathrm{a}=8 \\
& \mathrm{~b}=11
\end{aligned}
$$

Find: $\angle \mathrm{B}=$

$$
\begin{aligned}
\angle \mathrm{C} & = \\
\mathrm{c} & =
\end{aligned}
$$

Instead of $B=62.1, B$ can equal $117.9^{\circ}$
$\arcsin (.884)=62.1$ OR 117.9
therefore, if $\mathrm{B}=117.9$, then $\mathrm{C}=22.1^{\circ}$

## Law of Sines and Cosines Quiz

Since this is a SSA case, we may have 0,1 , or 2 solutions... Using law of sines:

$$
\begin{array}{ll|l|}
\frac{\sin 40}{8}=\frac{\sin B}{11} & \sin B=\frac{11 \sin (40)}{8}=.884 & \angle \mathrm{~B}=62.1 \\
\text { If } \mathrm{B}=62.1 \text {, then } \mathrm{C}=180-(62.1+40) & \angle \mathrm{C}=77.9 \\
\frac{\sin 40}{8}=\frac{\sin 77.9}{\mathrm{c}} \quad \mathrm{c}=\frac{8(\sin 77.9)}{\sin 40} & \mathrm{c}=12.17
\end{array}
$$

$$
\frac{\sin 22.1}{\mathrm{c}}=\frac{\sin 40}{8} \quad \mathrm{c}=\frac{8(\sin 22.1)}{(\sin 40)}=4.68
$$

$$
\begin{aligned}
& \angle \mathrm{B}=117.9^{\circ} \\
& \angle \mathrm{C}=22.1^{\circ} \\
& \mathrm{c}=4.68
\end{aligned}
$$

117.9
8) To find the distance across a lake, a surveyor took the following measurements:

What is the distance across the lake?
Once we recognize that the distance across the lake is the 3rd side of a triangle, we can use law of cosines to solve.
$c^{2}=a^{2}+b^{2}-2 a b(\cos C)$
$c^{2}=17.22+28.41-44.24(.799)$
$c^{2}=10.28$

the distance is approximate 3.21 miles
9) A sailor at sea looks at coordinates on the following map: How far is the paradise island from his home?
We have 2 sides of the triangle: 50 and $30 \ldots$.
Then, using geometry, we can figure out the included angle! ("parallel lines cut by a transversal -- alternate interior angles congruent"; then, angles on straight line add up to $180^{\prime \prime}$ )

law of cosines:
$c^{2}=(50)^{2}+(30)^{2}-2(50)(30)(\cos 100)$
$c^{2}=3400-3000(-.174)=3921$
therefore, the distance is approx. 62.6 miles

10) Triangle GUM has sides measuring 7,8 , and $13 .$. What are the angle measures?

## What is the area of the GUM?

Step 1: Sketch the triangle

Step 2: Find an angle
given 3 sides, we'll use law of cosines

$$
\begin{gathered}
g^{2}=u^{2}+m^{2}-2 u m(\operatorname{CosG}) \\
49=64+169-2(104)(\operatorname{CosG}) \\
-184=-208(\operatorname{CosG}) \\
\mathrm{G}=27.8 \text { degrees }
\end{gathered}
$$

Step 4: Find last angle

$$
\begin{gathered}
\mathrm{G}+\mathrm{U}+\mathrm{M}=180 \text { degrees } \\
27.8+32.2+\mathrm{M}=180 \\
\mathrm{M}=120 \text { degrees }
\end{gathered}
$$

To check solutions, can use law of sines for all.. Also, note: $u$ is slightly larger than $g$ and, angle U is slightly larger than G . Then, M is much larger than G and U (as is m is larger than g and u )

Law of Sines and Cosines Quiz ... and, Area

Step 3: Find a second angle given 2 sides and an included angle, we can use law of sines

$$
\begin{aligned}
& \frac{\sin \mathrm{G}}{\mathrm{~g}}=\frac{\sin \mathrm{U}}{\mathrm{u}} \\
& \frac{\sin (27.8)}{7}=\frac{\sin \mathrm{U}}{8} \\
& \sin \mathrm{U}=\frac{8 \sin (27.8)}{7} \\
& \mathrm{U}=32.2 \text { degrees }
\end{aligned}
$$

## AREA of GUM:

$$
\begin{aligned}
\text { Area }=\frac{1}{2} u m \sin (\mathrm{G}) & =\frac{1}{2}(8)(13) \sin (27.8) \\
& =24.25 \text { sq. units }
\end{aligned}
$$

11) Find the area of the interior of the triangle.
a) Use the trig area formula $\frac{1}{2} \mathrm{ab}(\sin (\mathrm{C}))$
b) Then, use Heron's formula to check your answer.
a) since we have 2 sides and included angle, we can use the trig area formula

$$
\text { Area }=\frac{1}{2}(13)(25.75) \operatorname{Sin}\left(18^{\circ}\right)=51.7 \text { sq. units }
$$

$\mathrm{r}=13$
$\mathrm{i}=25.75$
$\mathrm{T}=18$ degrees
b) To use Heron's formula, we need to know all 3 sides...

We can use law of cosines to get side $t$ :

$$
\begin{aligned}
\mathrm{t}^{2} & =(13)^{2}+(25.75)^{2}-2(13)(25.75) \cos \left(18^{\circ}\right) \\
& =169+663-669.5(.951) \\
& =195.27
\end{aligned}
$$

$$
\text { so, } \begin{aligned}
\mathrm{r} & =13 \\
\mathrm{i} & =25.75 \\
\mathrm{t} & =13.976
\end{aligned} \quad \mathrm{~s}=\frac{\mathrm{r}+\mathrm{i}+\mathrm{t}}{2}=26.363
$$

$$
\text { area }=\sqrt{26.363(26.363-13)(26.363-25.75)(26.363-13.976)}
$$

$$
t=13.976
$$

$$
=\sqrt{2675}=51.7 \text { محمrم }
$$

12) How tall is the tower?
method 1: use law of sines in the left triangle to find b . Then, use trig functions (sine) to find h in the right triangle
method 2: use tangent in large right triangle use tangent in small right triangle set equations equal to each other to find $x$ then, use trig functions (tangent) to find h

method 1:

Using geometry properties:
parallel lines cut by transversal, alternate interior
angles are congruent --37.6
sum of interior angles of triangle is $180---43.7$
therefore, upper angle of left triangle is $8.7^{\circ}$

Use law of sines to find length of $b$ :

$$
\begin{aligned}
& \frac{\sin (37.6)}{b}=\frac{\sin (8.7)}{30} \\
& b=\frac{30(\sin (37.6))}{\sin (8.7)}=121.0
\end{aligned}
$$

method 2:

$$
\mathrm{h}=87.48
$$

small triangle: $\tan (46.3)=\frac{h}{x} \longrightarrow x=\frac{h}{\tan (46.3)}$
large triangle: $\tan (37.6)=\frac{h}{x+30}$

$$
\begin{aligned}
& .770=\frac{\mathrm{h}}{\frac{\mathrm{~h}}{1.046}+30} \\
& \mathrm{~h}=\frac{.770 \mathrm{~h}}{1.046}+23.1 \quad .2638 \mathrm{~h}=23.1 \\
&
\end{aligned}
$$

One more question:
A parallelogram has side lengths 12 and 15.
If the longer diagonal has length 20, what is the length of the shorter diagonal?
SOLUTION on next page $\rightarrow$

A parallelogram has side lengths 12 and 15.
The longer diagonal has length $20 \ldots$
What is the length of the shorter diagonal?
We need to find the angles of the parallelogram...
Using law of cosines:

$$
\begin{aligned}
& c^{2}=a^{2}+b^{2}-2(a)(b) \cos C \\
& 20^{2}=12^{2}+15^{2}-2(12)(15) \cos \mathrm{C} \\
& 400=144+225-360 \cos \mathrm{C} \\
& \frac{31}{-360}=\cos \mathrm{C} \quad \mathrm{C}=94.9^{\circ}
\end{aligned}
$$

If $\mathrm{C}=94.9$ degrees, then the other angles are $180-94.9=85.1$ degrees (consecutive angles in parallelogram are supplementary) Then, use law of cosines again to find the other diagonal...

$$
\mathrm{d}^{2}=12^{2}+15^{2}-2(12)(15) \cos (85.1)
$$

$$
=144+225-360 \cos (85.1)
$$

$$
\mathrm{d}=18.39
$$
